# Overview

- Illumination Concepts
- Light Reflection model
  - Phong illumination model
- Light source types
- OpenGL lighting

# Illumination Concepts

- **Illumination:** transport of luminous flux from light sources between points via direct and indirect paths
- **Lighting:** computing radiance intensity reflected from a specific 3D point
- **Shading:** assigning colours to a pixel
- **Illumination Models:** Simple approximations of light transport

# Light-Surface Interaction

- Light and surface properties determine the illumination
- Light that strikes an object is partially absorbed and partially reflected
- The amount reflected determines the colour and brightness of the object (subtractive colours)
- Reflected light is scattered depending on the smoothness and orientation of the surface

# Modelling Surface Reflectance

- Compute light *reflected* by surface as *observed by viewer*
- Surface material tells *how much* of the incoming light is reflected
  - Type of light determines reflection model
- Intensity of observed light depends on *direction to light source* and *direction to viewer*

<https://tutorcs.com>

# Light Reflection Types

- *Ambient* light: comes from all directions, is scattered in all directions
- *Diffuse* light: comes from one direction, is scattered in all directions
- *Specular* light: comes from one direction, reflected in preferred direction (Highlights)

QQ: 749389476

<https://tutorcs.com>

# Ambient Reflection

- Ambient light is the same everywhere
  - Amount of reflected light of incoming intensity  $I_{\text{ambient},c}$  is *independent* to light source and viewer
- Intensity of reflected light observed by a viewer:  
$$L_{\text{ambient},c} = R_{\text{ambient},c} I_{\text{ambient},c}$$
  - $R_{\text{ambient},c}$  is ambient material property for colour  $c$  (percentage of red, green or blue ambient light reflected by surface)

<https://tutorcs.com>

# Diffuse Reflection

- Light is reflected in all directions
  - Amount of reflected light of incoming intensity *depends only on  $\cos \theta$  to light source*
- *Lambertian model* (cosine law / scalar product):
$$L_{\text{diffuse},c} = \frac{1}{\pi} \cos \theta (n^t d) I_{\text{diffuse},c}$$
  - $d$ : unit direction from surface point to light source
  - $n$ : unit surface normal

QQ: 749389476

<https://tutorcs.com>

# Specular Reflection

- Light is reflected preferable in *direction of perfect reflection*
  - Amount of reflected light of incoming intensity depends on direction of light source and to viewer

<https://tutorcs.com>

$$I_{\text{specular},c} = I_{\text{specular},c} (r^t v)^\sigma$$

- $r$ : unit direction of perfect reflection of  $d$
- $v$ : unit direction towards viewer position
- $\sigma$  is shininess exponent

# Surface Light Emissions

➤ Can make surface emit light, not just reflect light

➤ Simple model:

- Add emissive light intensities  $E_{t,c}$  to light intensities for each light type  $t$  and colour  $c$

- Does not illuminate other surfaces

(but can add a multiple point light sources behind surface or a directional light source for larger light emitting surfaces)

Assignment Project Exam Help

# Phong Illumination Model

- Putting everything together gives the Phong Illumination Model

- Consider monochromatic light (e.g. red, green or blue) and a single light source

- Depending on light source type, at a surface point the incoming intensity of different light types is  $I_a, I_d, I_s$

- The intensity of reflected light is

$$R_a I_a + R_d (n^t d) I_d + R_s (r^t v)^{\sigma} I_s$$

- **Summation** over all light sources for red, green, blue gives total intensity for all colours

- Note, Phong's illumination model is *not* physically accurate

# Light Source Types

- **Ambient** light source: light from the environment
- **Directional** light source: light from infinite distance in a specified direction
- **Point** light source: light from single point
- **Spot** light source: light emitted in a cone
- other light source: area light source, extended light source etc.

# Ambient Light Source

- An object not directly lit is still visible
  - Caused by light reflected from other surfaces
- Modelled by a simple ambient light source
  - Instead of complex surface reflections, specify *constant ambient light* for all surfaces
  - Defined solely by ambient RGB light *intensities*
- Intensity arriving at point p from an ambient light of intensity  $I_{\text{ambient},c}$  and colour c:

$I_{\text{ambient}}(p, I_{\text{ambient},c}) = I_{\text{ambient},c}$

QQ: 749389476

<https://tutorcs.com>

# Directional Light Source

- Light from a source *infinitely far away*
  - Defined by *intensities* of emitted RGB light of all types,
  - *direction*  $d, \|d\| = 1$  (no position)
- Intensity arriving at  $p$  from a directional light of intensity  $L_{t,c}$ :

程序代写代做CS编程辅导

$$I_{\text{directional}}(p, L_{t,c}) = L_{t,c}$$

Assignment Project Exam Help

Email: [tutorcs@163.com](mailto:tutorcs@163.com)

QQ: 749389476

<https://tutorcs.com>

# Point Light Source

- Light emitted *radially* from single point *in all directions*
  - Defined by *intensities* of emitted RGB light for all types,
  - *position*  $l$  (and  $r$  position),
  - constant, linear or quadratic *attenuation* ( $k_c, k_l, k_q$ )
- Intensity arriving at point  $p$  from a point light of intensity

$L_c :$

$$I_{\text{point}; l, k_c, k_l, k_q}(p, L_{t,c}) = \frac{L_{t,c}}{k_c + k_l \|p - l\| + k_q \|p - l\|^2}$$

Light

# Spot Light Source

- Light emitted in a *cone*
  - Defined by *intensities* of emitted RGB light for all types,
  - *position*  $l$ , *unit direction*  $s$ , *spot cut-off exponent*  $\tau$ ,
  - constant, linear *quadratic attenuation* ( $k_c, k_l, k_q$ )
- Intensity arriving at point  $p$  from an point light of intensity

$L_{t,c}$  :

$$I_{\text{spot}; l, s, \tau, k_c, k_l, k_q}(p, L_{t,c}) = \frac{(\max(0, \cos(\angle(p-l, s)))^\tau)}{k_c + k_l \|p-l\| + k_q \|p-l\|^2} L_{t,c}$$

# Light Source “Visibility”

- *Angle cut-off* for spot lights:
  - If position  $p$  is outside light cone ( $s^T d = \cos \gamma < \cos \delta$  with  $d = (p - l) / \|p - l\|$  and semi-angle  $\delta$ ), set  $I$  to 0
- Light source *behind* surface:
  - Diffuse and specular light only reflected if light source is in front of surface at  $p$
  - Set diffuse and specular light intensities from light sources to 0 if  $n^T d \leq 0$ 
    - $n$ : unit surface normal at  $p$
    - $d$ : unit direction from  $p$  to light source
  - This distinguishes between front and back of surfaces / polygons (also see two-sidedness)

# OpenGL lighting

- Fixed-function pipeline version of OpenGL (old version) uses specific functions to define lighting and material properties. And lighting effects are realised inside the OpenGL pipeline
- Shader version of OpenGL (new version) needs the programmer to write code in the main program and/or the shaders to implement lighting effects
- More details in the labs ...

# Surface Normal Vectors

- For lighting computations, OpenGL requires *normal vectors* of polygonal primitives
  - Orthogonal to surface, pointing outwards
  - Used to compute reflection angle
- Normals are sent to the vertex shader together with vertex coordinates
- Normals should be unit vectors
  - The function `normalize()` in shaders can be used to convert a vector to a unit vector:

`vec3 normalize(V);`

# Summary

- What is ambient, diffuse and specular light? How is the amount of reflected light for each light type computed?
- What is the Phong shading model?
- What are ambient, directional, point and spot light sources? How is the light intensity arriving from one of these light sources at a surface point computed?
- Distinguish light reflection types and light source types.
